

Serverless architecture helps developers by removing the need to manage servers. It automatically scales apps up or down depending on demand, which saves money and time. Developers can focus more on building features while the cloud provider takes care of things like updates, maintenance, and security, making it easier and faster to launch applications.

Progressive web apps (PWAs) are websites that work like mobile apps. They can send push notifications, work offline, and be added to a phone's home screen without needing to go through app stores. PWAs are built using regular web languages like HTML, CSS, and JS, making them easier and cheaper to build and update across different devices.

AI and Machine Learning are changing the way software is designed. They allow apps to learn from data and make smart decisions without being programmed for every situation. AI & ML are used to improve user experiences, spot problems early and make apps smarter and faster over time.

Cloud computing has three main service models: SaaS, PaaS and IaaS. SaaS (like Gmail) offers ready-to-use software over the internet. PaaS (like Google App Engine) gives developers tools to build and manage apps without worrying about hardware. IaaS (like Amazon EC2) provides virtual servers and storage, letting businesses run their own software with full control.
